

Pulse

Know the rush before it hits.

Oslo Sprint 2026

Busy stores have a blind spot.

While travelling in Oslo, I met my old Domino's employer. He owns the Burger King near Aker Brygge.

I told him about my startup. He said his problem is not knowing why his stores make sales.

And not knowing what happens nearby in real time, to forecast stock. Example: the trains stop working, and sales go up.

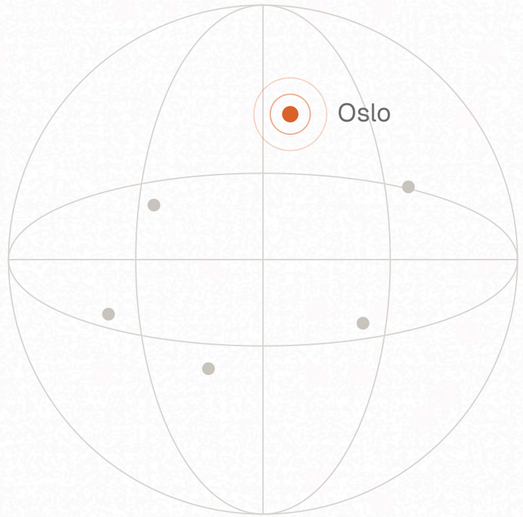

I worked at his Domino's in Majorstuen. When a rush hit, I was called in.

Many times the rush was over by the time I arrived. That means lost sales and unhappy customers.

It is a personal and real problem.

Solution: a real-time events analyser.

- Built and simulated on one real Burger King in Oslo, at Klingenberggata 5.
- Every decision comes from matching live events against the store's sales data.
- Any store with an address can get the same local picture.

Pulse watches the area for you.

- Real-time data for one local store.
- Events nearby.
- Transport and disruptions.
- Weather, and more.
- An hourly forecast of orders, the crew it needs, and why.

What we built in 48 hours.

MODEL

- A LightGBM model forecasts orders for every hour: a low, a likely and a high number.
- 30% fewer mistakes than a simple average, tested on a year it never saw.
- Runs inside the app, checked against the Python original.

LIVE DATA

- MET Norway Locationforecast and Frost observations.
- Entur Journey Planner, live vehicles, and 1.8 million past stop calls (SIRI-ET on BigQuery).
- Venue programmes scraped live with context.dev.

AGENTS AND STAFFING

- Gemini on Vertex AI: an event scout with Google Search grounding, a road camera watcher, a staffing overseer.
- Erlang C crew per hour and a set-covering shift plan (linear programming).
- 38 tests, including Norwegian Working Environment Act rules.

Our initial ICP.

- Busy fast food stores with a lot of walk-in traffic.
- More than 20 people on the payroll.
- Margins are thin, so extra unnecessary cost hurts them.

Why me

- Made 15k USD in e-commerce selling products.
- Coding since I was 10.
- Built an ERP for Etsy sellers, with paying users and power users.
- Building a startup right now with a co-founder who owned grocery stores and jewellery stores.
- Talking to real customers about Pulse tomorrow. The calls are booked.

Others are not hyper-local.

OTHERS

- Depend heavily on manual input from the store.
- Use a few broad area variables, not many local ones.

PULSE

- Reads many local signals around one address.
- Does it automatically.

Demo

Live, on the real store.

Thank you

Pulse

FAQ

01 What's your next step if you win tonight?

Launch it live. Talk to the customers booked for Monday. Connect the Burger King's till and train on real sales.

02 What's your biggest technical risk?

The model learned from simulated sales. We only know the real accuracy once a till is connected.

03 What did you leave out, and why?

Till connection, logins and more stores. We made one store work end to end first.

04 How will you get your first 100 users?

Start with the owner's own stores. One franchise owner runs many stores, so one yes brings several. Then walk into busy fast food stores in Oslo.

05 How have you tested this with users?

Not yet. The problem came from the owner, and the first customer calls are booked for Monday.

06 What legal hurdles could stop this?

Few. Pulse reads weather, trains, events and public road cameras, no personal data. Real staff rotas will need GDPR care.

07 Why hasn't anyone solved this before?

Tools forecast from past sales only. They don't see what is happening around the store right now. That is the part we built.
